

ABSTRACT

A cup holder for a motor vehicle includes a receiving device and a tempering device which is connected to an air-conditioning system. The air-conditioning system generates an air flow which is conveyed via an air-directing device to a beverage container which is retained in the receiving device.

In order to provide a cup holder which is easily accessible to an occupant and may be tempered at the same time, the receiving device may be pulled out of a housing while remaining connected to the air-conditioning system.
